

TD 7: Emptiness Test for Büchi Automata, Partial-Order Reduction

Exercise 1 (Büchi Emptiness Test). Consider an execution of Algorithm 1 on some Büchi automaton $\mathcal{B} = (\Sigma, S, s_0, \delta, F)$.

At each point during the DFS, we define the *search path* as the sequence of visited states for which the DFS call has not yet terminated (in the order in which they are visited), and the *explored graph* of \mathcal{B} as the subgraph containing all visited states and explored transitions. We call an SCC of the *explored graph* *active* if the search path contains at least one of its states. A state is *active* if it is part of an active SCC in the explored graph (it is not necessary for the state itself to be on the search path). The *active graph* is the subgraph of the explored graph induced by the active states.

For all strongly connected component $C \subseteq S$ of \mathcal{B} , we call *root of C* the state of C that is visited first during the DFS, i.e. the node r_C such that $r_C.num = \min\{s.num \mid s \in C\}$ at the end of the DFS. We define similarly the root of an SCC in the explored graph.

Algorithm 1 Depth-first-search

1. $nr = 0$;
2. $hash = \{ \}$;
3. $dfs(s_0)$;
4. exit;

$dfs(s)$:

1. add s to $hash$;
 2. $nr = nr + 1$;
 3. $s.num = nr$;
 4. **for all** $t \in succ(s)$ **do**
 5. **if** t not in $hash$ **then**
 6. $dfs(t)$
 7. **end if**
 8. **end for**
-

1. Show that an inactive SCC in the explored graph is also an SCC of \mathcal{B} .
2. Show that the roots of the SCCs in the active graph are a subsequence $r_1 \dots r_m$ of the search path, and that an activated node s is in the active SCC of r_i if and only if $i < m$ and $r_i.num \leq s.num < r_{i+1}.num$, or $i = m$ and $r_i.num \leq s.num$.
3. Show that Algorithm 2 maintains the following invariants:
 - the stack W contains the sequence $(r_1, C_1) \dots (r_m, C_m)$ where $r_1 \dots r_m$ is the sequence of roots of the active graph, and C_i is the active SCC of r_i ,

- for all nodes s , $s.active$ is *true* if and only if s is active.
4. Show that Algorithm 2 returns *true* iff the language of the input Büchi automaton is empty, and that in that case, it terminates as soon as the explored graph contains a counterexample.
 5. Adapt Algorithm 2 to test emptiness of a generalized Büchi automaton with acceptance sets F_1, \dots, F_n .
 6. Compare with the nested DFS algorithm from the lectures.

Algorithm 2 Emptiness Test

```
1.  $nr = 0$ ;  
2.  $hash = \{ \}$ ;  
3.  $W = \{ \}$ ;  
4.  $dfs(s_0)$ ;  
5. return true;  
  
dfs(s):  
1. add  $s$  to hash;  
2.  $s.active = true$ ;  
3.  $nr = nr + 1$ ;  
4.  $s.num = nr$ ;  
5. push  $(s, \{s\})$  onto  $W$ ;  
6. for all  $t \in succ(s)$  do  
7.   if  $t$  not in  $hash$  then  
8.      $dfs(t)$   
9.   else if  $t.active$  then  
10.     $D = \{ \}$ ;  
11.    repeat  
12.      pop  $(u, C)$  from  $W$ ;  
13.      if  $u$  is accepting then  
14.        return false  
15.      end if  
16.      merge  $C$  into  $D$ ;  
17.    until  $u.num \leq t.num$ ;  
18.    push  $(u, D)$  onto  $W$ ;  
19.  end if  
20. end for  
21. if  $s$  is the top root in  $W$  then  
22.  pop  $(s, C)$  from  $W$ ;  
23.  for all  $t$  in  $C$  do  
24.     $t.active = false$   
25.  end for  
26. end if
```

Exercise 2. Fix a set of atomic propositions AP, and $\Sigma = 2^{\text{AP}}$. Recall that $\sigma, \rho \in \Sigma^\omega$ are *stuttering equivalent*, written $\sigma \sim \rho$, when there exist infinite integer sequences $0 = i_0 < i_1 < \dots$ and $0 = k_0 < k_1 < \dots$ such that for all $\ell \geq 0$,

$$\sigma(i_\ell) = \sigma(i_\ell + 1) = \dots = \sigma(i_{\ell+1} - 1) = \rho(k_\ell) = \rho(k_\ell + 1) = \dots = \rho(k_{\ell+1} - 1),$$

where $\sigma(i) \in \Sigma$ denotes the letter at position i in σ .

A language $L \subseteq \Sigma^\omega$ is *stutter-invariant* if for all stuttering equivalent words $\sigma, \rho \in \Sigma^\omega$, we have $\sigma \in L$ if and only if $\rho \in L$.

1. Show that if φ is an LTL(AP, U) formula, then $L(\varphi) = \{\sigma \in \Sigma^\omega \mid \sigma, 0 \models \varphi\}$ is stutter-invariant.

A word $\sigma \in \Sigma^\omega$ is *stutter-free* if, for all $i \in \mathbb{N}$, either $\sigma(i) \neq \sigma(i + 1)$, or $\sigma(i) = \sigma(j)$ for all $j \geq i$.

2. Show that for all $\sigma \in \Sigma^\omega$, there exists a unique $\sigma' \in \Sigma^\omega$ such that σ' is stutter-free and $\sigma \sim \sigma'$.
3. Given $a \in \Sigma$, we write a for the formula $\bigwedge_{p \in a} p \wedge \bigwedge_{p \notin a} \neg p$. That is, $\sigma, i \models a$ if and only if $\sigma(i) = a$.
 - (a) Give a formula $\psi_{a,a}$ in LTL(AP, U) such that for all *stutter-free* words $\sigma \in \Sigma^\omega$, we have $\sigma, 0 \models \psi_{a,a}$ if and only if $\sigma, 0 \models a \wedge X a$.
 - (b) Let $a, b \in \Sigma$ with $a \neq b$. Give a formula $\psi_{a,b}$ in LTL(AP, U) such that for all *stutter-free* words $\sigma \in \Sigma^\omega$, we have $\sigma, 0 \models \psi_{a,b}$ if and only if $\sigma, 0 \models a \wedge X b$.
4. Let φ be any LTL(AP, X, U) formula. Construct by induction on φ an LTL(AP, U) formula $\tau(\varphi)$ such that for all *stutter-free* words $\sigma \in \Sigma^\omega$, we have $\sigma, 0 \models \varphi$ iff $\sigma, 0 \models \tau(\varphi)$.
5. Let φ be an LTL(AP, X, U) formula such that $L(\varphi)$ is stutter-invariant. Show that $L(\varphi) = L(\tau(\varphi))$.
